INTRODUCTION

During June 1982, a suppression project was conducted against the western spruce budworm (WSBW), Choristoneura occidentalis Free., on the Carson National Forest (NF) and State and private lands in the Moreno Valley. This report documents the objectives, methods, and results of this suppression project.

During the years 1976 to 1981, western spruce budworm-caused defoliation increased from approximately 81,760 to 135,025 acres on the Carson NF. In the Moreno Valley, defoliation increased from fewer than 1,000 acres in 1979 to approximately 37,780 in 1981.

Based on an environmental analysis,¹ the alternative direct suppression was selected to mitigate the effects of this western spruce budworm outbreak on a portion of the Carson NF and on State and private lands in the Moreno Valley.

Early in 1982, project plans were prepared to aerially treat with insecticides approximately 70,000 acres of budworm-infested Federal, State, and private lands. The criteria for selecting treatment areas were based on a strategy which called for suppressing early stage infestations only (1 to 3 years of visible defoliation) to obtain lasting suppression results. Based on this strategy, the following areas were aerially treated with insecticides during June 1982: (1) El Rito and Tres Piedras Ranger Districts, Carson NF, 34,265 acres; (2) Questa Ranger District, Carson NF, 1,488 acres; (3) Moreno Valley, State and private lands, 32,594 acres.

OBJECTIVES

Objectives were to:

1. Reduce WSBW populations to as low a level as possible so that predators and parasites, in conjunction with density independent factors, such as weather, exert considerable population regulation.
2. Keep tree damages below economic levels.
3. Prevent spread of WSBW infestations onto adjacent uninfested lands.
4. Prevent severe defoliation.

PROJECT ORGANIZATIONAL STRUCTURE

The project was organized into two distinct zones under the direction of a single administrative team. Zones were established basically because of the need to operate from two separate airport facilities.

¹ The Record of Decision for the Western Spruce Budworm Management Plan, Final Environmental Impact Statement, Carson National Forest, dated October 27, 1981.

The Carson NF zone consisted of treatment areas 1 and 2 (figures 1 and 2). Spraying operations for the Carson NF zone were based at the Taos Airport. The State and private zone consisted of treatment area 3 (figures 3 through 8) and spray operations were based at the Angel Fire airstrip.

Personnel from Forest Pest Management, State and Private Forestry, Southwestern Region; Carson NF; New Mexico Department of Agriculture; and the New Mexico Department of Natural Resources administered the project. Additional personnel from Forest Pest Management, Northern Region, and Washington Office provided assistance. Appendix C contains organizational charts.

INSECTICIDES

Carbaryl (Sevin 4 oil²) was applied at 0.5 gallon per acre (1 pound active ingredient). Carbaryl has proven effectiveness against the WSBW in the Southwest.

Bacillus thuringiensis (B.t.) was applied at 1 gallon per acre (8 billion international units active ingredient). B.t. has been extensively tested against the WSBW with varying success. A 1981 pilot test in New Mexico produced satisfactory results leading to the decision to use B.t. operationally.

The insecticide strategy was to treat sensitive and riparian areas with B.t. and treat the remaining areas with carbaryl.

Background information on both carbaryl and B.t., including environmental hazards, can be found in Appendix B, Draft Environmental Impact Statement, Carson National Forest, dated February 20, 1981.

SPRAY BLOCKS

Treatment areas (figures 1 through 8) were divided into spray blocks, except for the Red River treatment area which was considered as one spray block. Each spray block was designed to make foliage and larval development as uniform as possible, have access for population sampling, and have good identifiable natural and manmade boundaries.

² Union Carbide Corporation trade name for carbaryl insecticide; 4 pounds active ingredient per gallon.

Names and gross acreages of the treatment blocks were as follows:³

<u>Forest Service zone</u>		<u>State and private zone</u>	
<u>Spray block</u>	<u>Acreage</u>	<u>Spray block</u>	<u>Acreage</u>
1. Biscara Canyon	5,500	1. American Creek	6,500
2. Hopewell	7,000	2. Nine Mile Creek	6,200
3. Long Canyon	4,500	3. Agua Fria-Saladon	8,000
4. Rock Creek	4,800	4. Mutz	4,300
5. Tusas Mountain	7,000	5. Hematite Creek	4,800
6. Kiowa Mountain	7,600	Total	29,800
7. Red River	2,000	<u>B.t.</u>	1,780
Total	38,400	Total	31,580
<u>B.t.</u> Total	1,039		

TIMING OF SPRAY APPLICATION

For maximum efficiency, carbaryl was applied when 20 percent of the budworm population was in the fifth instar. B.t was applied when 50 percent of the budworm population was in the fourth larval instar. To determine the average larval instar percentage, sampling began on May 26, 1982, and continued until June 16, 1982, on the Carson NF zone; and began on May 28, 1982, and continued until June 17, 1982, on the State and private zone.

Developmental sampling consisted of cutting two 15-inch apical, mid-crown branches from an open-grown, 30- to 60-foot tall, Douglas-fir at each of 10 developmental sample plots on each spray block. In the field laboratory, all larvae were removed, placed in alcohol, and the instar determined. Average percentage of the budworm population in each instar was computed for each sampling date and each spray block.

WEATHER FORECASTING AND MONITORING

Local weather forecasts were provided each day to zone directors. These forecasts were obtained by the project meteorologist from the National Weather Service office in Albuquerque, New Mexico. National Oceanic and Atmospheric Administration meteorologists used onsite weather data collected the previous day and telephoned to Albuquerque to adjust their forecast to local situations.

³ The actual acreage treated differs slightly due to the availability of insecticides. Tables 1 through 4 display actual acreage treated.

APPLICATION

The pesticides were applied using turbine-powered fixed-wing aircraft. The VMD, as determined by the D-Max method (Maksymiuk 1963),⁴ ranged from 180 to 200 microns, depending on nozzle orientation, for carbaryl, and 276 microns for B.t.

Two observation helicopters were used to direct spraying operations on each zone. Observers in these helicopters directed spray aircraft by hovering at each end of the spray swaths. Aerial observers checked to see that spray aircraft were spraying within treatment block boundaries, had proper spray swath overlap, shut off over sensitive areas, and insured that safety procedures were followed.

Spraying of carbaryl began on June 13, 1982, and continued until June 21, 1982, on both the Carson NF and State and private zones. B.t. was sprayed on June 18, 1982, on the Carson NF zone, and started on June 12, 1982, and continued until June 17, 1982, on the State and private zone. Tables 1 through 4 show the spray dates and acres treated for each spray block.

SPRAY DEPOSIT ASSESSMENT

Spray deposition was estimated by placing Sudan Black cards for carbaryl and white Kromekote cards for B.t. within the spray blocks early in the morning just prior to spraying. Two cards were placed in a clearing near each cluster plot. If possible, cards were placed at least one tree height in distance from any other tree so as not to be in the spray shadow of a tree. Fifty cards were placed on each spray block. Plastic cardholders developed by the Missoula Equipment Development Center were used to hold the cards.

No dye was added to the carbaryl spray mixture. Droplets were counted on the cards at the field laboratory. Using a template, spray droplets in 4 square centimeters in the center of each card were tallied. The mean number of spray droplets per square centimeter per card was then calculated.

For one B.t. spray area on the State and private zone, white Kromekote cards were used and Rhodamine B dye was added to the spray mixture. Spray droplets were tallied as described for carbaryl.

Spray deposit on the six Carson NF zone spray blocks ranged from 9.4 to 36.8 drops per square centimeter, averaging 18.1 drops per square centimeter (table 5). This droplet density was sufficient to attain good mortality levels.

TABLE 5. Average spray deposit on each spray block, Carson NF, 1982
WSBW suppression project

Spray block	Average spray deposit drops per square centimeter
Kiowa	19.1
Tusas-Willow	19.7
Biscara-Martinez	9.1
Hopewell	36.8
Red River	9.4
Rock Creek	<u>14.6</u>
	Spray project average 18.1

On the State and private zone, spray deposit on the five carbaryl blocks ranged from 5.2 to 9.0 drops per square centimeter, averaging 7.4 drops per square centimeter. The one area monitored during B.t. spraying showed 6.9 drops per square centimeter. These results are presented in table 6. Although the droplet densities are less than is generally desired, the percent mortality and residual population levels resulting from the spray application reached satisfactory levels. Appendix A displays spray deposit data by plot.

ENVIRONMENTAL MONITORING

The USDA Fish and Wildlife Service monitored the aquatic environment of three small creeks--Bobcat, Tusas, and Rock--within the Carson NF zone during spray operations. Monitoring consisted of: (1) Taking substrate samples prior to treatment with a Surber sampler to determine aquatic insect diversity and relative abundance, and (2) obtaining 10-minute drift samples every hour for several hours during the morning of treatment days.

Aquatic monitoring revealed that insecticide drift caused by wind currents and temperature variations in the local topography around Bobcat Creek resulted in a minor setback for aquatic insect fauna. This setback was considered temporary. The aquatic insect fauna in Tusas and Rock Creeks experienced no adverse effects from the insecticide carbaryl. Detailed methods and results are presented in a separate report (Kennedy and Sanchez 1982)⁵ on file at Forest Pest Management, Albuquerque, New Mexico.

Wildlife personnel assigned to the Carson NF monitored the effects of the spray operation on avians on the Carson NF zone. No adverse effects were observed.

On the State and private zone, the New Mexico Department of Agriculture, Division of Agricultural and Environmental Services, Bureau of Pesticide Management, monitored the aquatic and atmospheric environments. Air samples were taken near spray block boundaries before and during spray operations. Water samples were taken from streams in or near spray blocks prior to spraying, 1 hour after spraying, and at various times 2 to 30 days after spraying. No pesticide was detected by the air samples. Only four water samples had detectable levels of carbaryl. No carbaryl was detected in the water samples after 8 days postspray.

<u>B.t.</u>	
Hematite Creek	6.9

Results are presented in a separate report (Lasswell 1982)⁶ on file at Forest Pest Management, Albuquerque, New Mexico, and at New Mexico Department of Agriculture, Las Cruces, New Mexico.

EVALUATING PROJECT EFFECTIVENESS

Effectiveness of the pesticide treatments was evaluated by measuring larval mortality of the 1981-82 budworm generation. Larval mortality was determined by sampling the budworm population on each spray block 1 day prior to spraying and 7 and 14 days after spraying.

Sampling design consisted of 25 plots, each a 3-tree cluster, per spray block. Plots were established throughout spray blocks near roads and trails. The three trees constituting a sample plot were located within 1 acre. The plot constituted the primary sampling unit. Plot means were computed by averaging larvae per 100 buds for each branch sampled on each tree, and then averaging the 3 trees. Larval means and standard errors were calculated for each spray block. Sampling was performed in the usual manner and is described in detail on page 87, USDA Forest Service, Western Spruce Budworm Suppression and Evaluation Project Using Carbaryl 1977, Progress Report No. 1, R-3 78-11.

Carson National Forest Zone

On the Carson NF zone, mean percent WSBW mortality (unadjusted) for the Tres Piedras and Red River treatment areas was 81.6 and 91.6, respectively. WSBW larvae per 100 buds were 4.5 for Tres Piedras and 1.3 for Red River at 14 days after treatment. Prespray, 7- and 14-day postspray mean larval densities, and percent mortality for each treatment area and spray block are presented in table 7. Appendix B contains the mean larvae per 100 buds for each cluster sample plot for prespray and 7- and 14-day postspray samples on each spray block.

State and Private Zone

Average percent mortality (unadjusted) for the carbaryl-treated blocks was 72.8. The average percent mortality for the B.t. areas that were monitored was 58.8. Prespray and 14-day postspray larval densities (larvae per 100 buds) were used to calculate these percentages. Seven-day postspray larval samples were taken to show mortality trends. These data are presented in table 8.

Fourteen-day postspray larval densities ranged from 1.8 larvae per 100 buds on the Mutz block, to 5.3 larvae per 100 buds on the Agua Fria-Saladon block. These densities represent 80.6 percent and 65.1 percent mortality, respectively. B.t.-treated areas averaged 3.5 larvae per 100 buds at 14 days postspray, a 58.8 percent mortality. Appendix B shows mean larvae per 100 buds for each cluster sample plot for prespray and 7- and 14-day postspray samples.

PROJECT COSTS

The total project costs were \$636,500. A breakdown of expenses by zone follows.

<u>Item</u>	<u>Carson National Forest zone</u>	<u>State and private zone</u>
Insecticides		
Carbaryl and carrier	\$135,776	\$116,000
<u>B.t.</u>	5,088	12,590
Aerial application	47,813	57,037
Helicopter services	7,882	21,000
Sampling, monitoring, and administrative expenses	<u>114,441</u> \$311,000	<u>118,873</u> \$325,500

Treatment costs per acre were as follows: Carson NF zone, \$8.70; State and private zone, \$9.99.

CONCLUSIONS

Carson National Forest Zone

The spray project was successful by the stated objectives. Percent mortality and residual larval numbers per 100 buds for the Tres Piedras treatment area, 81.5 and 4.53, respectively, are at acceptable, but not excellent, levels. These estimates are based on all sample plots within spray boundaries. They include sample plots which were unintentionally missed or received low insecticide deposit.

Considering the rapid budworm population buildup in the west division of the Carson NF, areas not treated in 1982 may require treatment in 1983 if any long-term protection is to be realized.

The primary objective on the Red River treatment area was to provide foliage protection in 1982; this objective was obtained. Further, future defoliation can be expected unless the WSBW populations in adjacent areas collapse.

State and Private Zone

Reduction of the budworm population from average prespray levels of 11.77 larvae per 100 buds to 3.20 larvae per 100 buds at 14 days postspray (carbaryl areas) meets the stated objectives of the spray project. Such low residual densities are expected to result in populations below damaging levels for several years without re-treatment. Migration and reinfestation from adjacent forest lands is not expected to be significant due to geographical barriers and lack of contiguous host-type areas.

RECOMMENDATIONS

During this operational suppression project, considerable time and money were expended sampling budworm larvae for insecticide efficacy. It is recommended, for operational projects, the sampling effort be reduced as a cost-saving measure. The following are suggestions to reduce sampling costs and effort:

1. Reduce the number of branches per tree sampled to one.
2. Perform only one postspray sample.
3. Reduce the number of prespray plots, since population variability appears to be less during this sampling period.
4. Increase the number of sample plots during the postspray period to maintain the same level of precision as the prespray sample.
5. Remove and count larvae from sample branches on drop cloths in the field, rather than in a laboratory trailer.

These suggestions will reduce the time and manpower necessary to perform pre- and post-spray sampling. While the precision of the estimates may be somewhat reduced, it will be adequate for the purpose and need of the data.

APPENDIX C

ORGANIZATION CHARTS

FIGURE 1. Project administrative team for the 1982 western spruce budworm suppression project

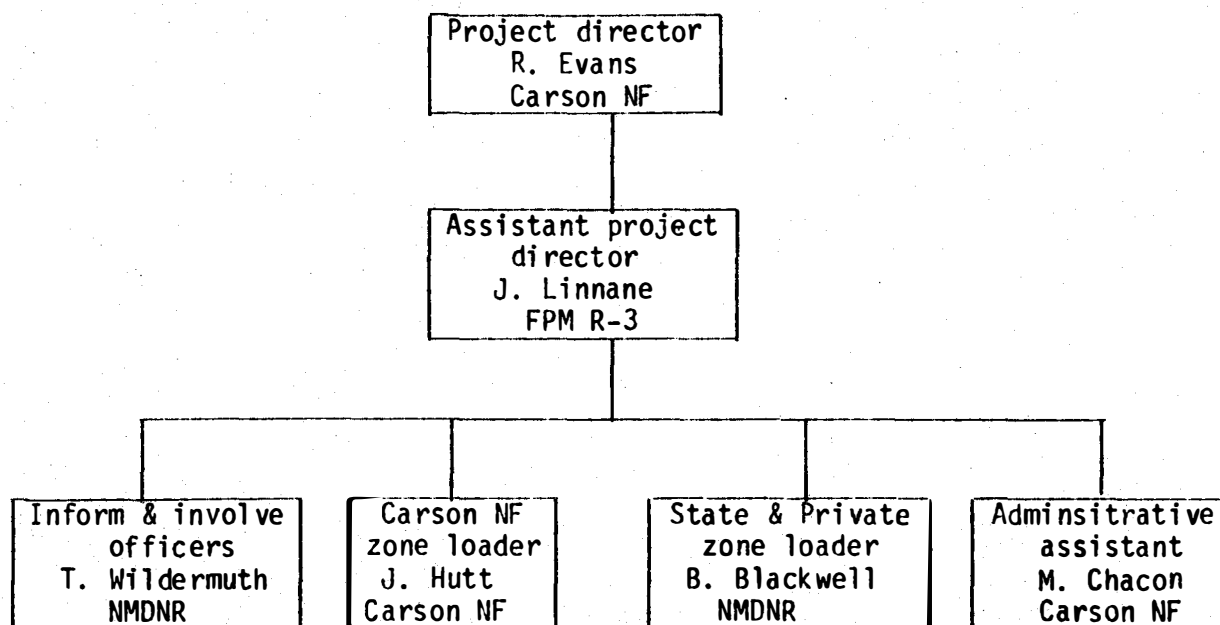

FIGURE 2. Carson National Forest zone organization chart for the 1982 western spruce budworm suppression project

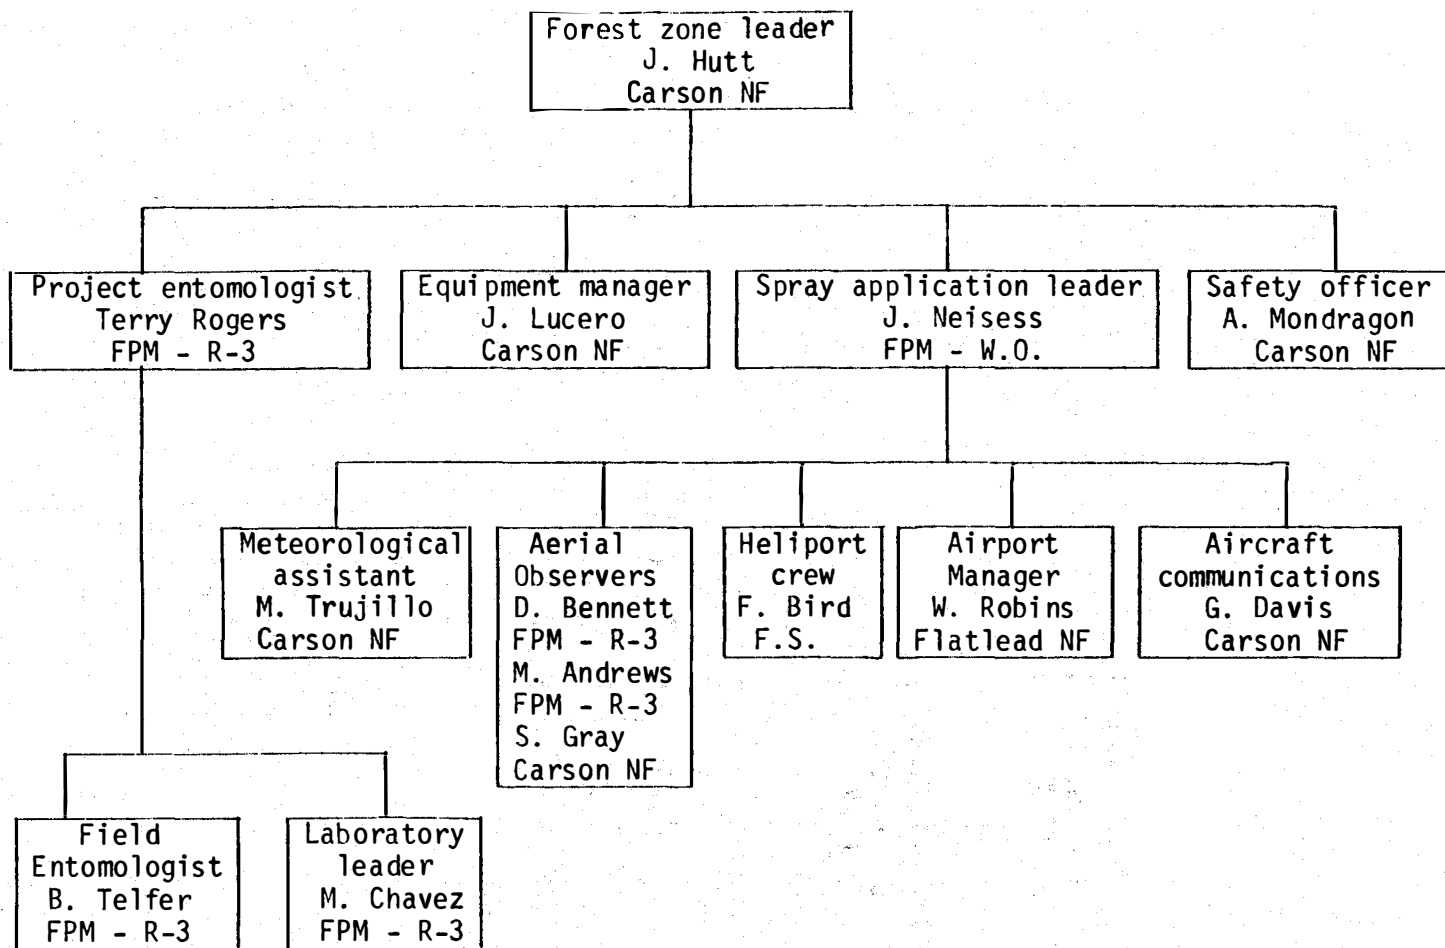

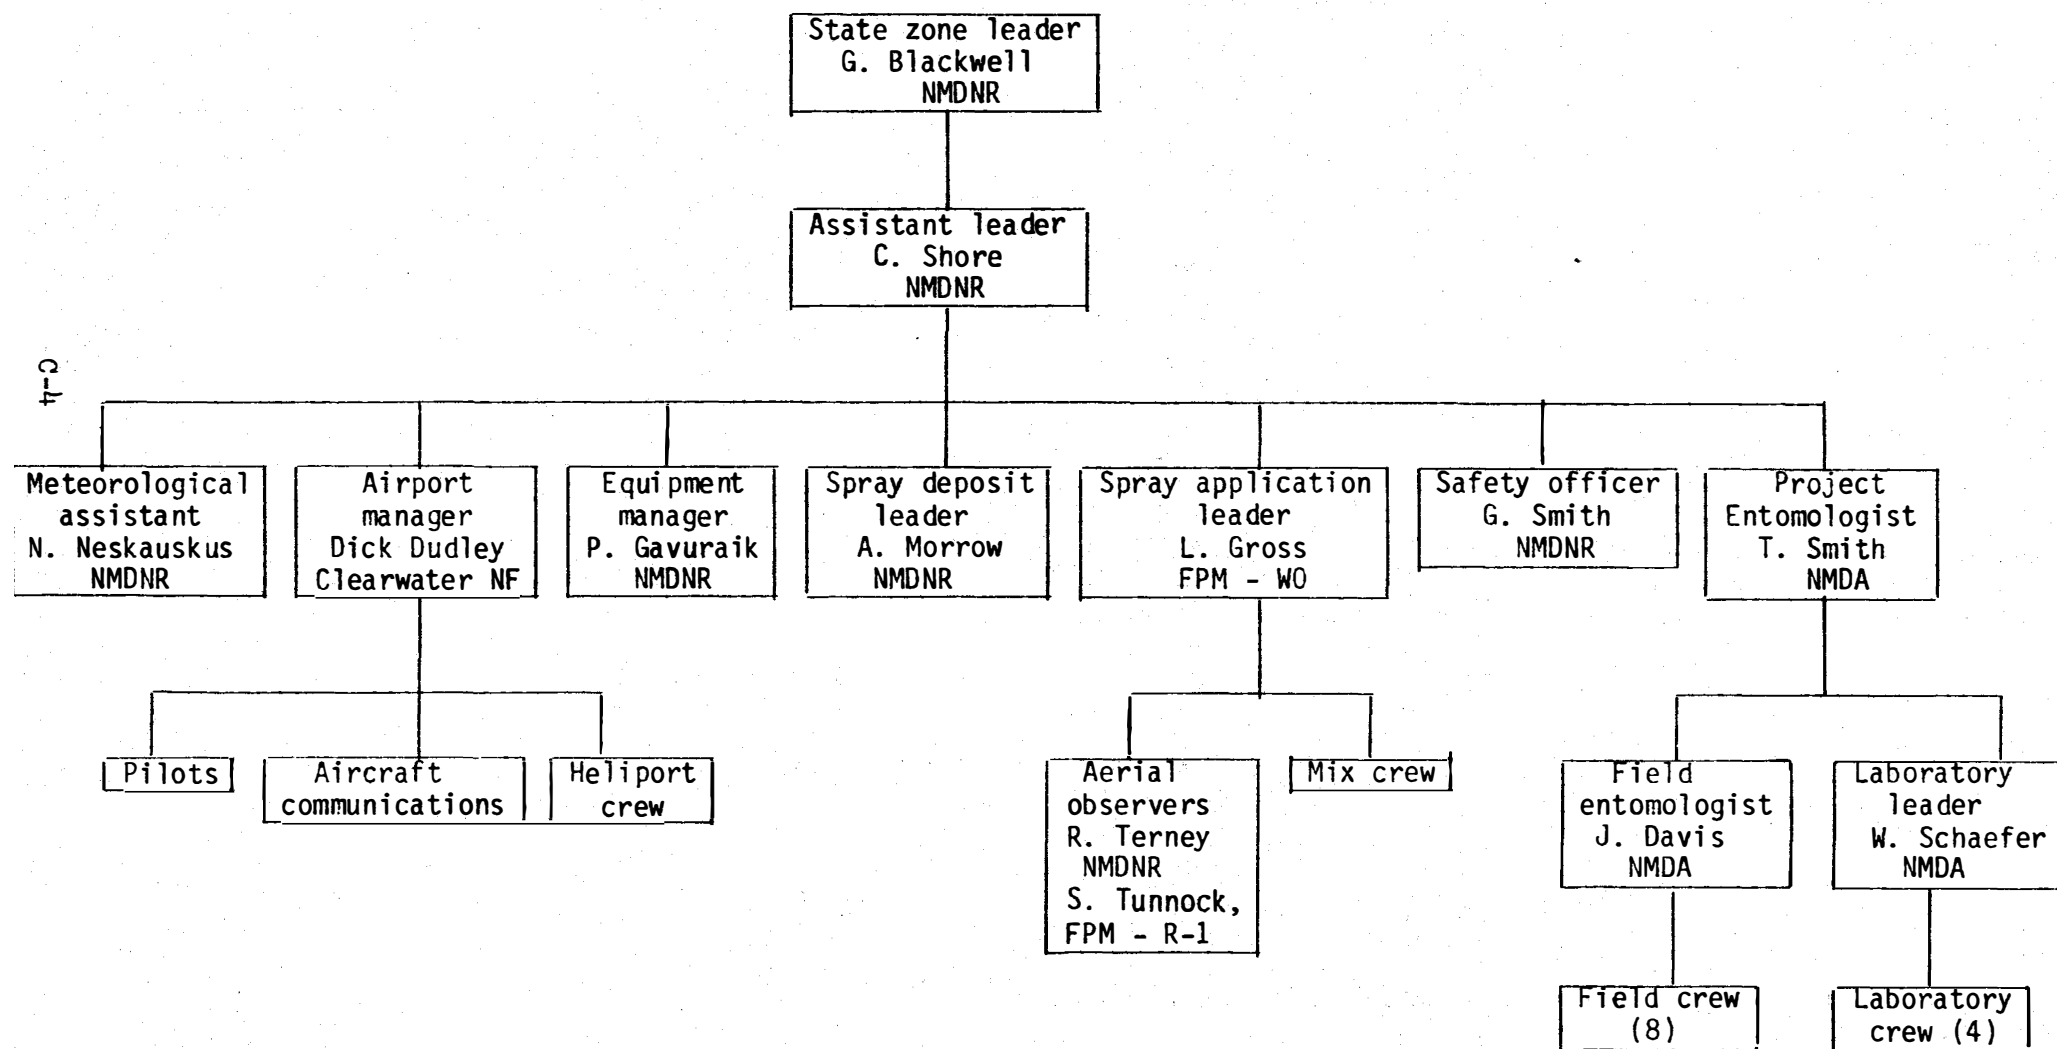

FIGURE 3. State and private zone organization chart for the 1982 western spruce budworm suppression project

Pesticides used improperly can be injurious to man, animals, and plants. Follow the directions and heed all precautions on the labels.

Store pesticides in original containers under lock and key--out of the reach of children and animals--and away from food and feed.

Apply pesticides so that they do not endanger humans, livestock, crops, beneficial insects, fish, and wildlife. Do not apply pesticides when there is danger of drift, when honeybees or other pollinators are visiting plants, or in ways that may contaminate water or leave illegal residues.

Avoid prolonged inhalation of pesticide sprays or dusts; wear protective clothing and equipment if specified on the label.

If your hands become contaminated with a pesticide, do not eat or drink until you have washed. In case a pesticide is swallowed or gets in the eyes, follow the first aid treatment given on the label, and get prompt medical attention. If a pesticide is spilled on your skin or clothing, remove clothing immediately and wash skin thoroughly.
